25

26 **Abstract**

27 Long-term peritoneal dialysis (PD) therapy results in functional and structural
28 alteration of the peritoneal membrane, including epithelial-to-mesenchymal
29 transition (EMT). Interleukin 6 (IL-6) is a local pleiotropic cytokine,
30 hypothesized to play an important role in EMT. This study was designed to
31 investigate the role of IL-6 in EMT and peritoneal membrane dysfunction in
32 long-term PD patients by assessing the level of IL-6 in dialysate and exploring
33 the relationship between IL-6, the related signaling pathway JAK2/STAT3, and
34 EMT, using in vitro cellular and molecular techniques. Plasma and dialysate
35 levels of IL-6 were significantly higher in PD ultrafiltration failure patients
36 compared to those in patients without ultrafiltration failure and were negatively
37 correlated with measures of PD adequacy. In vitro, IL-6 treatment changed
38 human peritoneal mesothelial cell phenotype from a typical cobblestone-like to
39 a fibroblast-like appearance and increased cell viability. IL-6 treatment
40 increased α -SMA and VEGF expression but decreased E-cadherin expression.
41 IL-6 treatment activated the JAK/STAT signaling pathway. However, the
42 JAK2/STAT3 inhibitor WP1066 prevented IL-6-induced activation of the
43 JAK2/STAT3 pathway and EMT. We conclude that IL-6 promotes the EMT
44 process, possibly by activating the JAK2/STAT3 signaling pathway. IL-6 may
45 serve as a novel therapeutic target for preventing EMT, and preservation of the
46 peritoneal membrane may arise from these studies.

52

53

54 **Introduction**

55

56 Peritoneal dialysis (PD) has drawn increasing attention as a common
57 therapeutic method for end-stage renal disease (ESRD) other than
58 hemodialysis and renal transplantation. However, long-term PD therapy is
59 known to result in functional and structural alterations in the peritoneal
60 membrane (7). Peritoneal pathology can be induced by several stresses
61 inherent in PD therapy, for example exposure of the peritoneal membrane to
62 PD fluid, catheter trauma, and peritonitis (26).

63

64 Interleukin 6 (IL-6) is a pleiotropic cytokine that plays an important role in
65 multiple pathological and physiological processes. It was found that increased
66 circulating level of IL-6 predicted poor outcome in patients with haemodialysis
67 and PD (21). In a model of acute peritoneal inflammation, fibrosis was strictly
68 dependent on IL-6 via IL-6-mediated T helper 1 cell effector commitment and
69 the emergence of STAT1 (signal transducer and activator of transcription-1)
70 activity within the peritoneal membrane (8). It was observed that IL-6 levels
71 were higher in drained dialysate than in the circulation, suggesting that the
72 peritoneal membrane produces local IL-6 during PD (19).

73

74 The epithelial-to-mesenchymal transition (EMT) is a process by which
75 epithelial cells lose their cell polarity and cell-cell adhesion and gain migratory
76 and invasive properties to become mesenchymal stem cells. EMT is essential
77 for numerous physiological and pathological processes including wound
78 healing (31), fibrogenic diseases (e.g. peritoneal fibrosis, glomerular fibrosis),
79 and renal dysfunction in diabetic nephropathy (1, 11). Several biomarkers for
80 EMT have been identified, such as the loss of the E-cadherin (an epithelial
81 adhesion protein), the upregulation of the α -smooth muscle actin (α -SMA, a
82 mesenchymal marker) and the upregulation of the vascular endothelial growth
83 factor (VEGF, a signalling protein involved in both vasculogenesis and
84 angiogenesis) (34).

85

86 The Janus Kinase/Signal Transducer and Activator of Transcription (JAK/STAT)
87 pathway is a pleiotropic cascade essential to signal transduction of cytokines

88 from the cell membrane to the nucleus. It has been reported to mediate
89 various cellular functions, including gene activation and cell proliferation,
90 differentiation and apoptosis (6). JAK/STAT pathway contributed importantly to
91 synthesis of extracellular matrix proteins (29). The analysis of glomeruli and
92 tubulointerstitium in kidney biopsies in diabetic nephropathy patients exhibited
93 increased expression of JAK/STAT pathway (2).

94

95 IL-6 was associated with increased expression of several pro-fibrotic (18) and
96 pro-inflammatory genes (25), and was found as a promoter of the JAK/STAT
97 pathway (14). Recent study showed that IL-6 can specifically activate STAT3
98 via its corresponding receptor (IL-6R), and therefore can lead to activation of
99 the JAK/STAT signaling pathway (30). In the research area of PD care, despite
100 the evidence of EMT of peritoneal mesothelial cells in patients undergoing PD,
101 few studies exist on the relationship between IL-6, the related signaling
102 pathway (JAK2/STAT3) and the EMT.

103

104 The objective of the current study therefore was to investigate the relationship
105 between IL-6 and peritoneal membrane injury and the possible mechanism of
106 IL-6-induced EMT through the JAK2/STAT3 signaling pathway. WP1066, an
107 inhibitor of JAK2/STAT3, was used to investigate the role of JAK2/STAT3 in
108 the process of EMT.

109

110 **Materials and methods**

111 ***Clinical epidemiology***

112 **Patients**

113 A cohort consisted of 40 ESRD patients between 1st of September 2015 and
114 31st August 2016 were recruited, from the Nephrology Centre of the First
115 Affiliated Hospital of Zhengzhou University, Henan, China. The study was
116 approved by the Ethics Committee of Zhengzhou University. Written informed
117 consent was obtained from all patients before enrollment.

118 Patient recruitment criteria are shown in Table 1. Patients were separated into
119 2 groups [ultrafiltration failure (UFF) and adequate UF], according to the
120 International Society for PD guidelines (16), which are based on peritoneal
121 equilibration test (PET) for volume and small solute clearance. After 2000 ml of
122 4.25% dextrose-containing dialysate is left in the peritoneal cavity for 4 hours,

123 less than 400 ml of UF indicates UFF, and dialysate/plasma creatinine ratio
124 (D/PCr) of more than 0.7 is consistent with the rapid small molecule transport
125 status often seen in UFF. Patient data included demographic-clinical [age,
126 gender, BMI, body surface area (BSA), PD duration], laboratory (serum
127 albumin, Hs-CRP, hemoglobin) and PD adequacy measures (total Kt/v urea,
128 peritoneal Kt/v urea, renal Kt/v urea, urine output, 24 hours ultrafiltration,
129 dialysate glucose exposure), the peritoneal equilibration test (PET) (4 hours
130 ultrafiltration, D/PCr), and the plasma and dialysate IL-6 levels .

131

132 **IL-6 level**

133 ELISA was used to measure the level of IL-6 in collected plasma and
134 peritoneal dialysate fluid (PDF) samples according to manufacturer's
135 instructions (CSB-E04638h, CUSABIO, Wuhan, China). Plasma was taken
136 during peritoneal equilibration test and immediately frozen at -80°C until
137 analysis. PDF was collected after overnight dwell (8-10 hours) before stored in
138 at -80°C. Samples were thawed once only during the aliquoting process prior
139 to analysis. Each sample was examined in duplicate. A Bio-Rad well-reader
140 (iMark, Bio-Rad, Hercules, CA, USA) was used with the absorbance at 450 nm.
141 Since the dialysate IL-6 level was influenced by ultrafiltration volume, it was
142 assessed as IL-6AR (IL-6 Appearance rate), calculated by dialysate
143 concentration×drained volume/dwell time (pg/min).

144

145 ***Cellular and molecular biology***

146 **Cell**

147 HPMCs were obtained Professor Pierre Ronco (TENON, Paris, France). Cells
148 were routinely cultured in Dulbecco's modified Eagle's medium (DMEM,
149 HyClone, Logan, Utah) supplemented with 10% fetal bovine serum (FBS,
150 Bioland, San Diego, California, United States), 100 UI/mL penicillin and 100
151 µg/mL streptomycin. Recombinant human IL-6 (Peprotech, New Jersey,
152 United States) was dissolved in DMEM.

153

154 **MTT assay**

155 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) (Sigma, St.
156 Louis, MO, USA) was used. HPMCs were seeded into a 96-well plate
157 (approximately 4,000 cells per well) and cultured to 40%–50% confluence.

158 Twenty μ L of MTT (5 mg/mL) was added to each well before further incubated
159 for another 4 hours. Subsequently, 100 μ L of dimethyl sulfoxide (DMSO) was
160 added to each well and mixed thoroughly, after culture medium was discarded.
161 Wells were then read at 490 nm using a microplate reader (iMark, Bio-Rad,
162 Hercules, CA, USA).

163

164 **Western blotting**

165 Protein from HPMCs was homogenized in lysis buffer and was quantified.
166 Each protein sample (30 μ g) was separated by 10% SDS-PAGE and
167 transferred onto a nitrocellulose membrane. At 4°C, the membrane was
168 simultaneously exposed overnight to mouse anti- α -SMA monoclonal antibody
169 (Wuhan Boster Biological Technology Ltd., Wuhan, China) in a 1:500 dilution,
170 to rabbit polyclonal anti-E-cadherin antibody, rabbit polyclonal anti-VEGF
171 antibody, rabbit polyclonal anti-JAK2 antibody (Proteintech, Manchester, UK)
172 and rabbit polyclonal anti-phospho-JAK2 antibody (Beijing Biosynthesis
173 Biotechnology Co. LTD., Beijing, China) in a 1:1000 dilution, to rabbit
174 monoclonal anti-phosphor-STAT3 (S727) antibody (Abcam, Cambridge, MA,
175 USA) and rabbit polyclonal anti-STAT3 antibody (Proteintech, Manchester, UK)
176 in a 1:5000 dilution, and to mouse monoclonal anti- β -actin antibody (Wuhan
177 Boster Biological Technology Ltd., Wuhan, China) a 1:4000 dilution. After
178 rinsing with 1 \times TBS, 0.1% Tween-20 solution four times every 5 minutes, each
179 membrane was incubated with horseradish peroxidase-conjugated secondary
180 antibody, goat anti-rabbit IgG or goat anti-mouse IgG (1:10,000 in dilution,
181 Proteintech, Manchester, UK) for 1 hour at room temperature. After another
182 wash with 1 \times TBS, 0.1% Tween-20 solution four times every 5 minutes, data
183 were analysed using an enhanced chemiluminescence Western blot detection
184 system (FluorChem E, proteinsimple, USA).

185

186 **RNA extraction and quantitative real-time PCR**

187 Total cellular RNA was extracted using RNAiso Plus (Takara Bio, Inc., Shiga,
188 Japan), and contaminating DNA was removed using RNAase-free DNase. The
189 DNA-free RNA was reverse-transcribed into cDNA using the RevertAid First
190 Stand cDNA Synthesis Kit (Thermo Fisher Scientific Inc., Massachusetts,
191 United States). Real-time fluorescence quantitative PCR was performed on
192 the 7500 Fast Real-Time PCR system using SYBR Green as double-stranded
193 DNA-specific dye in accordance with the manufacturer's instructions (Life
194 Technologies, Thermo Fisher Scientific, MA, USA). All primers used in the

195 PCR were designed using the Primer Express 2.0 software (Applied
196 Biosystems) and checked for homology using BLAST (see Table 2). The
197 relative mRNA expression level of the target genes in each sample were
198 calculated using the $2^{-\Delta\Delta CT}$ method.

199

200 **WP1066**

201 WP1066 (Selleck Chemicals LLC, USA) is an effective STAT3 pathway
202 inhibitor (23,27), a small molecule that can selectively block the
203 phosphorylation of JAK2 and STAT3.

204

205 ***Statistical analysis***

206 Data (continuous variable) were expressed as mean with standard deviation
207 (SD) or median with interquartile range (IQR) dependent on the data
208 distribution. Comparison between two groups was analysed using Student's T
209 or Mann Whitney test dependent on the data distribution. Pearson's correlation
210 test was used to assess possible correlation. A p-value < 0.05, two tailed, was
211 considered as statistical significance. All statistical analysis was carried out in
212 SPSS version 17.0.

213

214 **Results**

215 ***Clinical epidemiology***

216 **Level of IL-6 in plasma and dialysate in ESRD cohort**

217 Patient demographic and clinical characteristics, and particularly plasma and
218 dialysate IL-6 levels, stratified by PD/UFF status, are shown in Table 3. The
219 mean age of the cohort was 42 years, with 18 (45%) females. Not surprisingly,
220 characteristics demonstrating PD adequacy were different in PD patients
221 without UFF compared to those with UFF. However, no difference in other
222 patient characteristics was seen between the two subsets. IL-6 levels (both in
223 dialysate and plasma) were higher in UFF patients, compared to those in
224 patients with PD care.

225

226 Table 4 shows the correlation between IL-6 level in dialysate and the selected
227 patient characteristics. Level of IL-6 in dialysate was positively associated with
228 PD duration ($r = 0.39$) and D/PCr ($r = 0.63$) but negatively correlated with

229 measures of PD adequacy in relatively strong relationships ($r > 0.3$) in all
230 patients.

231

232 ***Cellular and molecular biology***

233 **Effect of IL-6 on cell morphology and viability**

234 Morphologic change of HPMCs occurred when cells were continuously
235 stimulated by IL-6 at a level of 50 ng/mL or higher for 5 days, with an apparent
236 dose-response effect. HPMCs converted into fibroblast-like appearance, from
237 the initial cobblestone-like cell (see Figure 1A). HPMCs showed an increased
238 cell proliferation with IL-6 stimulation (50 ng/mL, for 24 hours or longer),
239 compared to those not exposed to IL-6 but cultured in the same condition (see
240 Figure 1B).

241

242 **Effect of IL-6 on EMT related proteins in HPMC**

243 α -SMA and VEGF was significantly increased whereas E-cadherin was
244 downregulated with regard to the protein and mRNA expressions in IL-6
245 stimulated HPMCs at 24 hours (see Figure 2A-B for protein data and 2C-E for
246 mRNA data), with an apparent dose effect (none vs. 50 ng/mL vs. 100 ng/mL
247 IL-6). Data also showed that the stimulatory effects were time-dependent up
248 through the 24 hours tested (see Figure 3).

249

250 **Effect of IL-6 on JAK2/STAT3 signaling pathway in HPMC**

251 No difference in the total protein expressions of JAK2 and STAT3 was
252 observed before and after IL-6 treatment. However, the phosphorylated protein
253 of JAK2 and STAT3 were significantly increased (see Figure 4 A,C). Data also
254 showed that the activation effects were dose-dependent (Figure 4 A,B) and
255 time-dependent (Figure 4 C,D).

256

257 **Effect of WP1066 on JAK2/STAT3 pathway and EMT process**

258 P-STAT/STAT3 expression decreased significantly after treatment with 10 μ M
259 WP1066 for 24 hours (Figure 5), confirming that WP1066 was a JAK2/STAT3
260 inhibitor in our cell system. Therefore, 10 μ M WP1066 was used in the
261 experiments for preventing the JAK2/STAT3 signaling pathway. Figure 6

262 shows that treatment of HPMC with 10 μ M WP1066 alone for 24 hours did not
263 alter phosphorylation of JAK and STAT or total JAK and STAT expression,
264 compared to untreated cells. However, WP1066 prevented IL-6 from
265 increasing phosphorylation of JAK and STAT.

266 Addition of WP1066 eliminated the effect of IL-6 on α -SMA, VEGF and
267 E-cadherin (see Figure 7) and therefore prevented the EMT process.

268

269 **Effect of WP1066 on cell morphology and viability**

270 Morphologic change of HPMCs occurred when cells were continuously
271 stimulated by IL-6 at a level of 50 ng/mL for 5 days. When adding WP1066, the
272 effect of IL-6 was prevented (see Figure 8A). HPMCs showed an increased
273 cell proliferation with IL-6 stimulation (50 ng/mL, 24 hours), compared to those
274 without but cultured in the same condition. But this increasing cell viability was
275 prevented by WP1066 (see Figure 8B).

276

277 **Discussion**

278 PD and hemodialysis are well-established treatments for patients with ESRD.
279 PD has several advantages compared with hemodialysis, including a simpler
280 and less invasive procedure and the retention of residual renal function (3,4).
281 The peritoneum is a membrane with good penetration ability. PD clears
282 metabolic waste products and toxins and corrects water, electrolyte, and
283 acid-base disorders, using diffusion, ultrafiltration, and absorption. Peritoneal
284 ultrafiltration is affected by several factors such as transmembrane pressure
285 gradient, effective peritoneal surface area and aquaporin function (32).
286 Continuous exposure to conventional PD solutions contributes to progressive
287 peritoneal injury, which is an important source of local inflammation that can
288 result in adverse functional outcome such as higher peritoneal solute transport
289 rate (PSTR). Higher PSTR is a widely accepted risk factor for mortality and
290 technique failure in PD patients (24).

291

292 The IL-6 system (both dialysate and systemic) has been found to be
293 associated with variability in PSTR (13, 20). In our study, the levels of IL-6
294 (either plasma or dialysate) in patients with UFF were significantly higher than
295 those in patients without UFF. Furthermore, the dialysate level of IL-6 was
296 found to be correlated positively with PD duration and D/PCr, and negatively

297 with total Kt/v urea, peritoneal Kt/v urea, urine output, 24 hours ultrafiltration
298 and 4 hours ultrafiltration, suggesting that the dialysate IL-6 level is an
299 indicator of peritoneal UFF. Our results are in line with those from a previous
300 study which also showed that increased dialysate IL-6 level was associated
301 with more years doing PD therapy, and was a predictor of PSTR (5).

302

303 A recent study demonstrated that long-term overexpression of IL-6 might
304 promote fibrosis by regulating pro-fibrotic T-cell populations (8). In the mouse
305 model of peritoneal fibrosis, transfer of helper T cell type 1 effector T cell
306 secreting interferon- γ (IFN- γ) (under IL-6/STAT1 control) restored progression
307 to fibrosis in IL-6 knockout mouse by altering the normal control by
308 metalloproteinases of extracellular matrix turnover (8). In our study, HPMCs
309 treated with IL-6 showed morphological change towards fibroblast-like cells,
310 suggesting that the presence of overexpressed IL-6 may promote fibrosis in
311 peritoneal membrane.

312

313 The JAK2/STAT3 signaling pathway affects various basic cell functions in
314 response to extra-cellular cytokines and growth factors, such as cell growth,
315 differentiation and death (28). In association with the above classical pathway,
316 recently the signaling loop of IL-6/ glycoprotein 130 (gp130)/STAT3 was shown
317 to play a crucial role in the pathogenesis of lung fibrosis (17). In another study
318 the IL-6/Stat3/Akt signaling axis played a protective role in type 2
319 pneumocytes by regulating surfactant homeostasis (22). In the mouse model
320 of gp130^{F/F}, IL-6 trans-signaling via STAT3 is a critical modulator of the
321 lipopolysaccharide (LPS)-driven pro-inflammatory response through cross-talk
322 regulation of the TLR4/Mal signaling pathway (9). IL-6 administration *in vitro*
323 promoted STAT3 activity and collagen I expression and this study suggested
324 the multiple roles of IL-6 in renal fibrosis (33).

325

326 There were many proposed pathways associated with the pathogenesis of
327 peritoneal fibrosis during PD treatment such as the endothelial nitric oxide
328 synthase (eNOS)-NO signaling pathway (12), Serum response factor (SRF)
329 signaling (10), the phosphatidylinositol 3-kinase (PI3K)/AKT (also known as
330 PKB or protein kinase B) signaling pathway (15). However, the specific
331 involvement of IL-6 in peritoneal fibrosis is poorly understood. In our study,
332 data showed that the phosphorylation of JAK2 and STAT3 in HPMCs were
333 significantly increased in response to the treatment of IL-6, implying that IL-6

334 may be able to active JAK2/STAT3 signaling in vitro. The current study was the
335 first to investigate the possible effect of IL-6 on the JAK2/STATA3 in peritoneal
336 fibrosis. Although the mechanism is still largely unknown, our results at both
337 the clinical and cellular/molecular levels suggest that IL-6 may be an important
338 pro-EMT cytokine in PD therapy. This study provides initial and important
339 insights into the mechanisms of IL-6 in the EMT process of HPMCs and may
340 lead to therapeutic strategies to slow peritoneal fibrosis.

341

342 **ACKNOWLEDGMENTS**

343 The authors thank Professor Pierre Ronco (TENON, Paris, France) for providing
344 HPMCs cells. The authors thank Professor Guoqiang Zhao and Basic Research Centre,
345 Academy of Medical Science, Zhengzhou University for excellent technical assistance.

481

483 **Figure Legends:**

484

485 **Figure 1. Effect of IL-6 on HPMC morphology and viability**

486 HPMCs were incubated at 37°C in a 5% CO₂ atmosphere in DMEM medium without FBS.
487 (A) HPMC morphology, (I) without treatment, (II) treated with 30 ng/mL IL-6, (III) with 50
488 ng/mL IL-6, and (IV) with 100 ng/mL IL-6 for 5 days. Magnification, ×200.

489 Normal HPMCs showed a cobblestone-like appearance(I), and its morphology had no
490 obvious changes when cells were treated with 30 ng/mL IL-6. HPMCs which were treated
491 with increased concentration IL-6 displayed a fibroblast-like morphology (III and IV). N = 6
492 per group.

493 (B) HPMC viability, without treatment vs. treated with 50 ng/mL IL-6 for 24, 48 and 72
494 hours; Absorbance value at 490 nm.

495 Cell viability was increased by 50 ng/mL IL-6. Compared with the same time, the values of
496 the experimental groups were higher than that of no treatment group. * Statistical
497 difference ($p < 0.05$). N = 6 per group. Data are means \pm SE.

498

499 **Figure 2. Protein and mRNA expressions of E-cadherin, α -SMA, and VEGF in IL-6**
500 **cultured HPMCs at 24 hours**

501 Western blotting analysis for protein expression: (A), raw photo and (B), densitometry
502 analysis; β -actin as the housekeeping gene to normalize expression level. Real-time
503 fluorescence quantitative PCR for mRNA expression: (C), for E-cadherin, (D) for α -SMA
504 and (E) for VEGF; GAPDH as the housekeeping gene to normalize expression level.

505 The protein and mRNA expression of α -SMA and VEGF increased significantly following
506 exposure to IL-6, peaking at 100 ng/mL. On the contrary, the expression of E-cadherin
507 was downregulated by IL-6. *Statistical significant ($p < 0.05$) vs. no treatment. N = 6 per
508 group. Data are means \pm SE.

509

510 **Figure 3. Protein and mRNA expressions of E-cadherin, α -SMA, and VEGF in 50**
511 **ng/ml IL-6 cultured HPMCs at 24, 48 and 72 hours**

512 Western blotting analysis for protein expression: (A), raw photo and (B), densitometry
513 analysis; β -actin as the housekeeping gene to normalize expression level. Real-time
514 fluorescence quantitative PCR for mRNA expression: (C), for E-cadherin, (D) for α -SMA
515 and (E) for VEGF; GAPDH as the housekeeping gene to normalize expression level.

516 The expression of α -SMA and VEGF increased significantly following exposure to IL-6,
517 peaking at 72 h respectively. On the contrary, the expression of E-cadherin decreased as
518 the stimulus time of IL-6 extends. *Statistical significant ($p < 0.05$) vs. no treatment. N = 6
519 per group. Data are means \pm SE.

520

521 **Figure 4. Protein expressions of JAK2 and STAT3 in IL-6 cultured HPMCs at 24, 48**
522 **and 72 hours**

523 Western blotting analysis for protein expression: (A,C), raw photo and (B,D), densitometry
524 analysis; P-JAK2, phosphorylated JAK2; P-STAT3, phosphorylated STAT3; β -actin as the
525 housekeeping gene to normalize expression level.

526 (A,B) The relative protein expression of active JAK2/STAT3 increased significantly
527 following exposure to IL-6, peaking at 100 ng/mL, respectively. * Statistical significant ($p <$
528 0.05) vs. no treatment. N = 9 per group. Data are means \pm SE.

529 (C,D) The relative protein expression of active JAK2/STAT3 increased significantly
530 following exposure to IL-6, peaking at 72 h respectively. * Statistical significant ($p <$
531 0.05) vs. no treatment. N = 9 per group. Data are means \pm SE.

532

533 **Figure 5. The effect of WP1066 on the expression of P-STAT3/STAT3 at 24 hours**

534 Western blotting analysis for protein expression: (A), raw photo and (B), densitometry
535 analysis; β -actin as the housekeeping gene to normalize expression level. The relative
536 protein expression of active STAT3 (phosphorylated/total) decreased significantly in
537 exposure to 10 μ M WP1066; * $p < 0.05$ (vs. no treatment). N = 12 per group. Data are
538 means \pm SE.

539

540 **Figure 6. Phosphorylated and total protein expressions of JAK2 and STAT3 in**
541 **HPMCs with IL-6 and WP1066 treatment at 24 hours**

542 Western blotting analysis for protein expression: (A), raw photo and (B), densitometry
543 analysis; (I) no treatment (without IL-6, without WP1066); (II) IL-6 (with IL-6, without
544 WP1066); (III) IL-6+WP1066 group (with IL-6, with WP1066); (IV) WP1066 (without IL-6,
545 with WP1066); β -actin as the housekeeping gene to normalize expression level.

546 The relative protein expression of active JAK2/STAT3 increased significantly following
547 exposure to 100 ng/ml IL-6, * Statistical significant ($p < 0.05$) vs. no treatment. When
548 adding to 10 μ M WP1066, the activation of JAK2/STAT3 which was induced by IL-6 was
549 prevented obviously. N = 12 per group. Data are means \pm SE.

550

551 **Figure 7. Protein expressions of E-cadherin, α -SMA and VEGF in HPMCs with IL-6**
552 **and WP1066 treatment at 24 hours**

553 Western blotting analysis for protein expression: (A), raw photo and (B), densitometry
554 analysis; β -actin as the housekeeping gene to normalize expression level. (I) no treatment
555 (without IL-6, without WP1066); (II) IL-6 (with IL-6, without WP1066); (III) IL-6+WP1066
556 group (with IL-6, with WP1066); (IV) WP1066 (without IL-6, with WP1066). Real-time
557 fluorescence quantitative PCR for mRNA expression: (C), for E-cadherin, (D) for α -SMA
558 and (E) for VEGF; GAPDH as the housekeeping gene to normalize expression level.

559 The relative protein and mRNA expression of α -SMA and VEGF increased significantly
560 following exposure to 100 ng/ml IL-6, which also decreased E-cadherin expression, *
561 Statistical significant ($p < 0.05$) vs. no treatment. When adding to 10 μ M WP1066, the
562 expression changes of α -SMA, VEGF and E-cadherin prevented obviously. N = 9 per
563 group. Data are means \pm SE.

564

565 **Figure 8. Effect of WP1066 on cell morphology and viability in IL-6 treated HPMCs**

566 HPMCs were incubated at 37°C in a 5% CO₂ atmosphere in DMEM medium without FBS.
567 (A) HPMC morphology, cultured for 5 days; (I) no treatment (without IL-6, without
568 WP1066); (II) IL-6 (with IL-6, without WP1066); (III) IL-6+WP1066 group (with IL-6, with
569 WP1066); (IV) WP1066 (without IL-6, with WP1066). Magnification, \times 200. (B) HPMC
570 viability, cultured for 0 and 24 hours; Absorbance value at 490 nm.

571 IL-6 induced morphologic change of HPMCs and an increased cell proliferation. When
572 adding WP1066, the effect of IL-6 was prevented. Compared with no treatment, The
573 morphology and viability of HPMCs had no changes. * Statistical difference ($p < 0.05$)
574 between with and without treatment. N = 6 per group. Data are means \pm SE.

Table 1. Patient recruitment criteria

Eligibility criteria	Exclusion criteria
PD >3 months	Presence of systemic inflammatory disease, peritonitis or fluid overload 3 months;
≥18 years old	Malignant tumor;
blood pressure <140/90mmHg	Taking glucocorticoid or immunosuppressive agents during the past 1 year;
Hemoglobin A1C(HbA1C) <9%	Acute cardio cerebrovascular events that occurred in past 3 months;
PD solution: Dianeal Baxter company	Multiple organ dysfunction syndrome; Systemic inflammatory response syndrome.

Inclusion, meet all eligibility criteria; Exclusion, meet any exclusion criteria. PD, peritoneal dialysis.

Table 2. Sequences of mRNA

Gene Symbol	Forward Primer(5'-3')	Reverse Primer(5'-3')
E-cadherin	CTCTTCTCCGCCTCCTTCTT	TGATTCTGCTGCTCCTTGCTG
α -SMA	AAGATGACCCAGATCATGTT	TCATAGATGGGGACATTGT
VEGF	ATGACGAGGGCCTGGAGTGT	GGGATTTCTTGGGCTTTCGTTT
GAPDH	CCTCAAGATCATCAGCAAT	CCATCCACAGTCTTCTGGGT

Table 3. Patient characteristics and IL-6 levels

Characteristics	PD (n=20)	UFF (n=20)	p value
<i>Clinical-demographic</i>			
Age, years	43 ±14	41±15	0.6
Male	11(55%)	11(55%)	1.0
BMI	23.6±3.2	22.5±2.5	0.2
BSA, m ²	1.6±0.5	1.6±0.5	0.9
PD duration, months	24.85(10-40)	27.20(12-37)	0.4
<i>Laboratory measures</i>			
Serum albumin, g/l	30.1±3.5	30.2±3.2	0.9
Hs-CRP, mg/l	4.8±2.8	5.0±2.8	0.8
Hemoglobin, g/l	89.6±16.3	88.1±8.9	0.7
<i>PD adequacy</i>			
Total Kt/v urea	1.8±0.2	1.6±0.2	<0.01
Peritoneal Kt/v urea	1.6±0.2	1.4±0.1	0.04
Renal Kt/v urea	0.2±0.1	0.1±0.1	0.02
Urine output, ml/24h	713(200-1250)	400(50-700)	<0.01
24 h Ultrafiltration, ml/24h	628(200-1300)	100(-300-310)	<0.01
Dialysate glucose exposure, g/day	132.2±25.6	142.6±30.5	0.2
<i>peritoneal equilibration test (PET)</i>			
4 h Ultrafiltration, ml/4h	550(400-750)	30(-200-300)	<0.01
dialysate/ plasma creatinine (D/PCr)	0.6±0.2	0.8±0.1	<0.01
<i>IL-6 level</i>			
Plasma level (pg/mL)	20.7±5.0	69.3±16.5	<0.01
Dialysate level (IL-6 Appearance rate, pg/min)	96.1±20.5	448.0±51.6	<0.01

PD, patients under scheduled peritoneal dialysis care; UFF, patients occurred peritoneal ultrafiltration failure.

Table 4. Correlation test between IL-6AR level in dialysate with selected patient characteristics (all patients n=40)

Variable	r	p value
BSA	0.09	0.59
PD duration	0.39	0.01
Hs-CRP	0.27	0.09
Total Kt/v urea	-0.48	<0.01
Peritoneal Kt/v urea	-0.33	0.04
Urine output	-0.44	<0.01
24 hour Ultrafiltration	-0.81	<0.01
4 h Ultrafiltration	-0.78	<0.01
D/PCr	0.63	<0.01

PD, patients under scheduled peritoneal dialysis care; UFF, patients occurred peritoneal ultrafiltration failure; r, correlation coefficient.
